# AMMM - Course project

Master in Research and Innovation in Informatics

Ignacio Encinas Rubio, Adrián Jiménez Gonzalez {ignacio.encinas,adrian.jimenez.g}@estudiantat.upc.edu

Polytechnic University of Catalonia

19 de noviembre de 2022

#### Contents

- 1. Problem Statement
  - 1.1. Inputs & Outputs
- 1.2. Definitions 2. Integer Linear Programming Model
- 2.1. Variables
- 2.2. Constraints
- 2.3. Redundant constraints

- 3. Metaheuristics
  - 3.1. Greedy algorithm 3.2. Local Search

  - 3.3. GRASP
    - Parameter tuning
- 4 Results
  - 4.1. Time
  - 4.2. Quality of solutions

#### Problem Statement

#### Main requirements

- 1. Each contestant will play exactly once against each of the other contestants.
- 2. Each round will consist of  $\frac{n-1}{2}$  matches.
- 3. Players will play 50% of their games as white, 50% will be played as black.

## Subtle requirements

- A player can only play up to 1 game per round
- A player can't play against himself

# Problem Statement: Inputs & Outputs

## Inputs

- lacktriangle Number of contestants, n. Has to be odd
- $\blacksquare$  Matrix of points per day per player,  $p_{n\times n}$

# Outputs

■ Schedule with the set of pairings  $\{\{r_1, p_i, p_j\}, \ldots, \{r_n, p_k, p_h\}\}$  that maximizes total score. Ensured to be optimal if it's obtained through the ILP.

## **Problem Statement: Definitions**

In order to specify the constraints, we need to specify the sets and variables we're going to work with:

- $lackbox{ } M(x,y)$  matches played among x and y (1)
- $lackbox{ }R(r)$  matches played at round r (2)
- $lackbox{ }W(p)$  matches played by player p as white (3)
- lacksquare B(p) matches played by player p as black (3)
- ullet G(p,r) games played by p at round r (4)
- F(r) free players at round r (5)

- Each contestant will play exactly once against each of the other contestants.
- 2. Each round will consist of  $\frac{n-1}{2}$  matches.
- 3. Players will play 50 % of their games as white, 50 % will be played as black.
- 4. Players can play up to 1 match per round
- Objective function

Every set will be constructed from a boolean multidimensional array. matches[w][b][r] will be 1 whenever player w plays player b in round r, and 0 otherwise.

#### Set constructions

```
\begin{split} M(x,y) &= \{\{x,y,r\} & | \; \mathsf{matches}[x][y][r] = 1 \lor \mathsf{matches}[y][x][r] = 1 \quad \forall r \in [1,Rounds] \} \\ F(r) &= \{p & | \; \mathsf{matches}[p][o][r] = 0 \land \mathsf{matches}[o][p][r] = 0 \quad \forall o \in [1,n] \} \\ W(p) &= \{\{p,b,r\} & | \; \mathsf{matches}[p][b][r] = 1 \quad \forall r \in [1,Rounds], b \in [1,n] \} \\ B(p) &= \{\{w,p,r\} & | \; \mathsf{matches}[w][p][r] = 1 \quad \forall r \in [1,Rounds], w \in [1,n] \} \\ R(r) &= \{\{w,b,r\} & | \; \mathsf{matches}[w][b][r] = 1 \quad \forall w,b \in [1,n] \} \\ G(p,r) &= \{\{o,p,r\} & | \; \mathsf{matches}[p][o][r] = 1 \lor \mathsf{matches}[o][p][r] = 1 \quad \forall o \in [1,n] \} \end{split}
```

# Integer Linear Programming Model: Constraints

$$|M(x,y)| = 1 \quad \forall x, y \in P \mid x \neq y \tag{1}$$

$$|R(r)| = \frac{n-1}{2} \quad \forall r \in [1, \text{ Rounds}]$$
 (2)

$$|W(p)| = \frac{n-1}{2} \quad \forall r \in [1, \text{ Rounds}], \forall p \in P \quad \textbf{(3)}$$

$$|G(p,r)| \le 1 \quad \forall p \in P, r \in [1, \text{ Rounds}]$$
 (4)

- Each contestant will play exactly once against each of the other contestants.
- 2. Each round will consist of  $\frac{n-1}{2}$  matches.
- 3. Players will play 50 % of their games as white, 50 % will be played as black.
- 4. Players can play up to 1 match per round

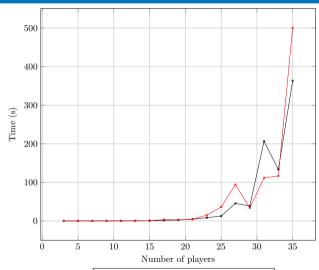

# Integer Linear Programming Model: Redundant constraints

Redundant constraints might appear to make the model faster but they seem make it slower in the long run

$$|M(x,x)| = 0 \quad \forall x \in P$$

$$|B(p)| = \frac{n-1}{2} \quad \forall r \in [1, \text{ Rounds}], p \in P$$

 $\longrightarrow$  ILP non-redundant  $\longrightarrow$  ILP redundant

### **Greedy cost function**

$$q(c, day) = c.points\_per\_day[day]$$

# Algorithm Greedy algorithm

- 1: Players ← Set of Players
- 2: rests  $\leftarrow \{\}$
- 3: for day in 0..days do
- 4:  $playersToRest \leftarrow filter Players(p) | p.hasNotRested$
- sortedPlayers  $\leftarrow$  sort playersToRest(p) by q(p,day) (DESC)
- 6: select  $p \in sortedPlayers[0]$
- 7:  $rests[day] \leftarrow p$

## Metaheuristics: Local Search

## Algorithm Local Search

1: for i in 0..days do
2: best\_swap\_points ← 0
3: best\_swap ← i
4: for j in 0..days do
5: change = EvaluateRestSwap(i,j)
6: if change > best\_swap\_points then
7: best\_swap\_points ← change
8: best\_swap ← j
9: rests[i] ↔ rests[best\_swap]

### Metaheuristics: GRASP

# **Algorithm** constructRCL(day)

- 1:  $q_{max} \leftarrow \text{sortedPlayers.first().points[d]}$
- 2:  $q_{min} \leftarrow \text{sortedPlayers.last().points[d]}$
- 3:  $RCL_{max} \leftarrow \{p \in sortedPlayers \mid p.points[d] >= q_{max} \alpha \cdot (q_{max} q_{min})\}$

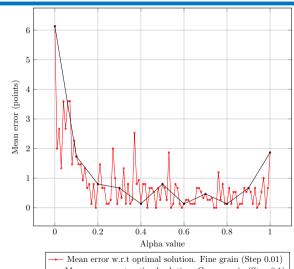

### **Algorithm** GRASP

- 1: rests  $\leftarrow \{\}$
- 2: for day in 0..days do
- 3:  $RCL \leftarrow constructRCL(day)$
- 4: select  $p \in RCL$  randomly
- 5:  $rests[day] \leftarrow p$

# **GRASP:** Parameter tuning

- Figure shows the arithmetic mean error with respect to the optimal solution for each of the instances.
- We keep the smallest alpha that gives the minimum mean error.

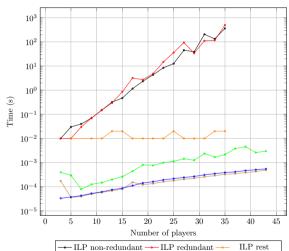

→ Mean error w.r.t optimal solution. Coarse grain (Step 0.1)

#### Results: Time

- Greedy and Local Search need approximately same time to reach the solution. They're fastest but their quality of the solution is too low.
- GRASP sacrifices some runtime performance to improve the quality of the solution.
- ILPs obtain the optimal solution at cost of being several orders of magnitude slower due to the complexity of creating valid pairings.
- ILP rest obtains the optimal solution just computing the rest day for each player. It is not much slower than GRASP and for large instances it can be even faster.

# Results: Quality of solutions

- Greedy offers the worst solution for every instance
- Greedy + Local Search improves the quality of the solution taking practically the same time as Greedy.
- GRASP commonly reachs the optimal solution, having a great improvement over Local Search.
